Abstract

**Objective:** Evaluate the current evidence regarding different aspects (epidemiological, histological, physiological and genetic) of male infertility caused by Y-chromosome microdeletion.

**Material and Methods:** A systematic review of articles from January 1st, 1996 and February 28th, 2014 present in two databases: MEDLINE and ScieLO. The search was performed with the MeSH descriptors "Y Chromosome", "Infertility" and Keyword "microdeletion".

**Results:** The literature indicates that deletion of AZF, especially AZFc, is related to azoospermia, oligozoospermia or even infertility. The absence of other loci is also underlined by the evidence: AZFa, AZFb and AZFd, even though the prevalence rates are not equidistant. Surveys also show changes in the male hormone physiology varying the levels of testosterone/LH/FSH as well as modifying the gonadal morphology in individuals affected by Y-chromosome microdeletion.

**Conclusion:** More research is needed focusing on possible deletions that the Y-chromosome may suffer, giving emphasis on their clinical outcomes and correlations with infertility.

Introduction

Infertility affects 10-15% of couples of reproductive age [1-4]. The contribution of factors related to male is between 30-50% [5]. Failures in spermatogenesis are among the main reasons with 50% of...
cases [6, 7]. However, more than 60% of these cases the origin of reduction in testicular function is unknown [7, 8]. Chromosomal abnormalities are confirmed as one of the common causes of male infertility, the incidence of around 20% is observed in men with azoospermia [9, 10].

Y-chromosome microdeletion has played a causal role in male infertility [7, 11]. Some studies show [5, 12] that the main genetic factors involved in male infertility are chromosomal abnormalities and Y-chromosome microdeletions. The microdeletion of azoospermia factor (AZF) on the Y-chromosome was discovered as a frequent genetic cause associated with male infertility [10]. Several researchers [1, 14-16] suggest that after the Klinefelter syndrome, the Y-chromosome microdeletions is among the most frequent genetic cause of male infertility.

In this sense, the present study was based on the following guiding question: what practical contributions to the scientific literature produced in the period of 1996-2014, has to offer feedback about the impact of the Y-chromosome microdeletion in male infertility? This review highlights male infertility as a major factor responsible for human infertility as well as the Y-chromosome microdeletion as a major etiological factor of the pathogenesis of this comorbidity. Thus, our objective was to evaluate the current evidence concerning to different perspectives (Epidemiological, histological, physiological and genetic) of male infertility caused by Y-chromosome microdeletion, formulating a systematic review of published studies on the subject. Our hypothesis is that, despite the growing interest on the subject, the correlation among deletions of certain genes located on the Y-chromosome and some phenotypes of infertility are not still adequately solid, thus meriting greater theoretical contributions subsidized by multicenter studies as well as research of recognized statistical support as meta-analysis.

Material and Methods

Systematic qualitative review whose selection of the studies was performed broadly through the Virtual Health Library (VHL), which hosts the recognized data bases. Initially, the following descriptors were used:

- #1 "Y-Chromosome" (Medical Subject Headings [MeSH]);
- #2 "Infertility" [MeSH];
- #3 "microdeletion" [Keyword];

Complementing search using the keyword "microdeletion" is justified because this term, though not cataloged in MeSH, is often used to characterize studies dealing with the issue the subject of this review. The results obtained led the research at the online database: Medical Literature Analysis and Retrieval System Online (MEDLINE). A similar search strategy was performed on the basis of SciELO (Scientific Electronic Library Online), using previously mentioned descriptors and equivalent in portuguese language. The period of time raised in the literature was January 1st, 1996 and February 28th, 2014. A reason to delimit the search for the period 1996-2014, was the lack of studies that focused on the Y-chromosome microdeletion and its correlation with male infertility.

The data compilation took place during the months of March and April 2014. The selection of manuscripts occurred primarily through the analysis of titles and abstracts/summaries. The analysis of the articles followed the predetermined eligibility criteria for the inclusion criteria: (1) articles that had in the title at least a combination of the terms outlined in the search strategy; (2) articles written in English, Portuguese or Spanish; (3) Articles that addressed Y-chromosome microdeletion and infertility; (4) Original studies with full text accessible via Portal of Journals of the CAPES (Coordenação de Aperfeiçoamento de Pessoal de Nível Superior), a virtual library created by the Brazilian Ministry of Health and that has restricted content to authorized users. The elements excluded: (1) non-original
studies such as Letters to the Editor, Prefaces, brief communication, Corrections/Erratum, Reviews, Editorials and Monographs. Manuscripts repeated in more than one database were counted only once.

Then, each sample item was read in its entirety, and the information was entered into a spreadsheet that included authors, year of publication, sample description of the study and main findings (Table 1). Some of the articles found were contemplating the theme of the male infertility correlated to other casuistics that it is not the Y-chromosome microdeletion, considering that this study focuses on male infertility as resulting from Y-chromosome microdeletion, correlated data to other elements were not analyzed. The search strategy was performed by two independent researchers, with disagreements decided in consensus with a third researcher senior.

Regarding the search strategy, this occurred in three phases. The first phase occurred in VHL, which we were taken to MEDLINE. In this first stage we use the following strategy: #1 AND #2 AND #3, yielding 190 articles of which 29 were selected. The second and third stages occurred in SciELO. The second stage used descriptors #1 AND #2 AND #3, yielding three articles of which one was selected. In the third phase the descriptors used #1 AND #2, yielding 10 items of which two were selected. In order to enhance the data analysis, the next stage involved the group, for heuristic reasons, of the results on three themes: “Epidemiological aspects of Y-chromosome microdeletion”; “Y-chromosome Microdeletion: Some histological and physiological characterizations" and "Microdeletion of Y chromosome: major sub-regions affected.” (Figure 1).

This was a literature review therefore no involving recruitment of patients. In this sense, ethical approval was not necessary. This revision is using the PRISMA protocol (http://www.prisma-statement.org/).

Results

According to the strategy adopted initially 203 manuscripts were found. Articles repeated in the course of the search strategy were computed only once. After reviewing the titles, abstracts and manuscripts entirely cited, the total of 32 articles were obtained and selected according to the eligibility criteria, being therefore excluded 171. The 32 studies were divided into three predetermined categories: “epidemiological aspects of Y-chromosome microdeletion”; “Y-chromosome Microdeletion: Some histological and physiological characterizations" and "Y-chromosome Microdeletion: major sub-regions affected." (Figure 1).

Given the importance of the category “Y-chromosome microdeletion: major sub-regions affected" and aiming at making the approach of the clear data, made to Table 2, which included authors, year of publication, patients with Y-chromosome microdeletion, percentage of carrier microdeletion sample in the following areas respectively - AZFa, AZFb, AZFc and other areas. Of the 32 selected studies 14 are from descriptive [1, 2, 4, 13, 24, 27-29, 31, 32, 34-37], 08 are cross-sectional [3, 5, 17, 18, 21, 25, 26, 33], 05 are experimental [7, 12, 19, 20, 38], 03 are case reports [22, 30, 39] and 02 are case-control studies [10, 23]. Studies have good methodological accuracy. The sample universe is quite heterogeneous, given the very design of the studies (22 case reports with 02 individuals up to 33 cross-sectional studies with 4, 441 individuals), age differences between individuals in the samples ranging from 17 years [10] to 66 years [21], as well as the origin of the patients who were: India [2, 23, 25, 35], Brazil [3, 31, 34, 36], China [4, 10, 17, 18], Iran [1, 7, 19, 21] Turkey [5, 26, 27], Italy [12,29], Germany [13], Chile [40], Korea [20], Denmark [37], USA [22], England [38], Mexico [30], Serbia [28] and Venezuela [32]. Because of this situation, the data becomes divergent and the comparative analysis becomes troublesome.

Discussion

Epidemiological aspects of Y-chromosome microdeletion

One hundred and forty four (10.80%) of 1,333 infertile men showed Y-chromosome microdeletion. The frequency of microdeletions was 11.75% (111/945) in the group of azoospermic patients, significantly higher compared with 8.51% (33/388) of oligozoospermic patients (P>0.05) [10]. Yq Microdeletion (long arm of the Y chromosome) were detected in ten patients in the study by Seung Hun et. al. [20]. Bor et. al. [37] tracked three (0.75%) Y-chromosome microdeletions in a total of 400 blood samples from men undergoing ICSI (Intracytoplasmic Sperm Injection).

In the sample composed to 80 men with infertility in southeast Turkey, the deletion of the Y-chromosome was found in one patient (1.3%) with normal karyotype and azoospermia [26]. Sachdeva et. al. [2] detected by analyzing 200 infertile men in India, microdeletions in 21 (10.5%). Among them, 13 were in cases of azoospermia and eight in cases of severe oligozoospermia. In the study of São Pedro et. al. [36], four (6.7%) of 60 infertile patients tested exhibited Y-chromosome microdeletion, two of whom were patients with severe oligozoospermia (P10 and P32) and two men with azoospermia (P47 and P57).

In evaluating 143 men with severe oligozoospermia and non-obstructive azoospermia, Mafra et. al. [3] reported that the Y-chromosome microdeletions were found in 4.2% of infertile men studied. And that by doing a separate analysis, were detected 3% (3/100) microdeletions in oligozoospermic group of patients and 6.9% (3/43) in the group of azoospermic. Faldalla et. al. [17] found microdeletions in 38 (11, 62%) of 327 patients with altered semen parameters. The authors emphasize that the Y microdeletion rates in patients with oligozoospermia, oligoaesthenozoospermia, oligoaesthenoteraatozoospermia and oligoteratozoospermia are respectively 12.07% (28/232), 10:41% (5/48) 9:52% (2/21) and 33.33% (1/3) [17].

Abid et. al. [25] by analyzing 100 men with severe oligoaesthenozoospermia and 100 with nonobstructive azoospermia showed Y-chromosome microdeletions in six (3%), of which three had azoospermia and three asthenoligozoospermia. The opinion of Çinar et. al. [27] is that of the 63 patients Y-chromosome microdeletion were observed in two patients with azoospermia and normal karyotype (46, XY). In one study [37], the frequency of Y-chromosome microdeletions was higher in men with azoospermia (2%) compared with oligozoospermic men (0.6%). Zhu et. al. [4], examining 312 infertile men in Chengdu (China) of which 14% (25/178) of the Y-chromosome microdeletions were found in the azoospermic patients and 8.2% (11/134) in the group of oligozoospermic. In the study of Khan, Ganesan and Kumar [23] there was an index deletion of 61.5% in cases of azoospermia, 11.1% in oligozoospermic patients and 16.6% in oligo-asthenospermic patients.

Totonchi et. al. [21] have reported 147 cases with Yq microdeletion who suffered azoospermia and 38 of them severe oligozoospermia. Deletion of the Y-chromosome was found in the study of Ristanovic et. al. [28] in 14 (15.6%) cases, nine with azoospermia and five with severe oligozoospermia. The analysis of an Italian study [29] the microdeletions occurred in 3.2% of unselected infertile men, 8.3% in men with non-obstructive azoospermia and 5.5% in men with severe oligozoospermia [29].

In the work of Saliminejad et. al. [1] microdeletion was not found in men with severe oligozoospermia. And, in the group with azoospermia 2/94 (2.13%) of the patients showed Y-chromosome microdeletions. Four of 60 (6.7%) infertile patients tested in a study [36] showed Y-chromosome deletion, two of which had severe oligozoospermia (P10 and P32) and 2 had azoospermia (P47 and P57 patients).

In a survey of 2012 [10] thirty four patients had chromosomal abnormalities among 144 with Y-
chromosome microdeletion. In the control group of the previously mentioned study, chromosomal abnormalities or microdeletions in AZF region [10] were not detected. Cytogenetic study [5] revealed seven (3.93%) Y-chromosome microdeletions. In Bor et. al. [37] chromosomal abnormalities were found in 6.1% of men with azoospermia and in 2.7% of the oligozoospermic men.

**Y-chromosome Microdeletion: Some histological and physiological characterization**

Regarding hormonal aspects evaluated in an Indian study [25], the concentrations of FSH (Follicle Stimulating Hormone) in patients with microdeletion were significantly lower when compared to those without microdeletions (P <0.017). The concentration of LH (Luteinizing Hormone) was significantly higher in patients with microdeletions when compared to those without microdeletion (P<0.019). Testosterone levels in patients with microdeletion were significantly lower compared to patients who had not microdeletions (P <0.0083). These evidences are in accordance with Faldalla et. al. [17] whose findings indicate that levels of testosterone, testosterone/LH of the group with microdeletions in the AZF region (azoospermia factor) was significantly lower when compared to the control group (P = 0.000). Moreover, the levels of FSH/LH were found significantly higher than those in the control group (p = 0.000).

However, Pandey et al. [24] show that hormonal levels (FSH, LH and testosterone) showed significantly higher (P <0.001) in relation to controls, when evaluated 64 men with infertility, of which 3% were in AZFc microdeletion. São Pedro et. al. [36] reported that the 4 patients with Y-chromosome microdeletion in their study, all male had high concentrations of serum FSH. Levels of testosterone and LH were within normal range except for patient P57 (azoospermic) who showed elevation of the serum LH and decreased testosterone.

Studies [13, 25] showed patients with microdeletion and severe aspects in testicular histology (Sertoly-only cells and stop at maturity) compared to non-affected by deletion. In other study [13], two other patients with a microdeletion in proximal Yq11 (patient H49 and HD23) had very small testis volumes (6–8 ml).

Nathanson et. al. [33] demonstrated that deletion of the segment gr/gr AZF region on the Y-chromosome doubling the chance of TGTC (Testicular germ cell tumor), with a three-fold increase for those with a family history of the disease. Deletion gr/gr was more strongly associated with seminoma (aOR 3.0, 95% CI 1.6-5.4, p=0.0004) compared with non-seminoma from TGCT (aOR 1.5, 95% CI 0.72-3.0, p=.29) [33]. In the point of view of Dada, Gupta and Kucheria [35] the patient 2 presented in cytopathology Sertoli cell-only syndrome. Patient #3 had deletions of the AZFa region and partial deletion of the AZFb region. In FNAC (Fine needle Aspiration Cytology), patient #3 showed Sertoli cell-only syndrome. The patients 6, 7 and 8 had deletions of the AZFc region of the Y-chromosome. Patients 6 and 8 showed hypospermatogenesis, and patient 7 stop of the maturation in the spermatocy II stage.

**Y-chromosome Microdeletion: Key affected subregions**

In the study by Fu et. al. [10] the deletion of AZFc subregion (54.17%) was the most frequent deletion in the AZF. Fifteen infertile patients (10.42%) had a deletion in AZFb subregion (13 azoospermic and two with severe oligozoospermia) and 13 (9.03%) men with azoospermia presented deletions in AZFa subregion. The types of extensive deletions involving two or three completed AZF regions included 2.08% of subregions AZFab, 2.08% of AZFac, 18.75% of AZFbc and 3.47% of AZFabc, respectively [10]. In Totonchi et. al. [21] the most frequent microdeletion was the AZFc region followed by regions AZFb +c+d, AZFb + c, AZFb,
AZFa and AZF a + c. Ristanovic et. al. [28] showed 64.7% deletions in AZFc region, 17.6% in the AZFa region and 17.6% in the AZFb region. Microdeletions in the AZF region of the Y-chromosome, particularly microdeletion of the AZFc region, represented a common genetic cause of idiopathic azoospermia and severe oligozoospermia in infertile men in Serbia [28].

Fernandez-Salgado et. al. [32] detected microdeletions in the AZFc region of the Y-chromosome in 3.4% of the patients. Choi et. al. [18] showed 8.5% Korean men had deletions in the segment gr/gr (P <0.003), 5.8% had deletions of the region b2/b3, 1.1% had deletions in the region b1/b3, 0.3% had deletions in the region B3/B4, totaling 15.6% subjects (P<0.001). The authors also indicate that partial deletions of AZFc region were more often found in men with insufficient spermatogenesis when compared with the control group [18].

Akin et. al. [5] reported that the AZFc region was the most frequently involved in the processes of microdeletion in affected subjects. And that one of the subject (patient 6) had microdeletion in 3 regions (AZFa, AZFb, AZFc) and another individual (patient 2) had microdeletions in AZFb and AZFc regions. All study subjects who had Y-chromosome microdeletion were azoospermic [5]. Gatta et. al. [12] observed that all the samples had a set of deletions in AZFc region (loci sY152 and sY158) regardless of their testicular phenotypes. About the AZFc region, an interesting finding in the study was Moghbeli-Nejad et. al. [19], in which variations in the number of copies of the studied markers in region AZFc of lymphocyte of infertile men (microdeletion and duplication) in all samples after exposure to increased radiation dose dependent. The frequency instability was significantly higher in samples from infertile men compared with fertile (p<0.001) [19].

Patients 1 and 2 from a study [37] presented the Y-chromosome contiguous microdeletion in the AZFc region, while patient 3 who had azoosperma, had deletions of noncontiguous in the AZFb and AZFc regions. No microdeletions were detected in AZFa region [37]. In Seung Hun et. al. [20] three patients showed deletion in the region AZFb-c and other seven had deletions in AZFc region. No involved new regions were found specifically with male infertility20. Saliminejad et. al. [1] detected a patient completed deletion of the AZFc region and another showed completed deletion of both AZFb and AZFc regions. Microdeletion was not found in the AZFa region. Balkan, Tekes and Gedik [26] founded microdeletions in AZFc and AZFd regions, but no microdeletion in AZFa region or AZFb. In Pandey et. al. [24] there was the frequency of 3% of the AZFc microdeletion region, and no mutations were observed in AZFa and AZFb regions, maybe due to selective use of sequences of markers.

Khan, Ganesan and Kumar [23] found ten patients with Yq deletion in AZFa and AZFc regions. In Sao Pedro et. al. [36], patients with azoosperma showed large deletions. Deletions located in the AZFa and AZFc regions were found in patient P47, while deletions in AZFb and AZFc regions were found in patient P57. Patients with severe oligozoospermia, P10 and P32, showed microdeletions that could not be detected by classical cytogenetic analysis methods, both showed normal morphology for chromosome Y. Patients P47 and P57, on the other hand, showed a chromosomal constitution 46, XY, del(Y)(q11) [36].

In the search of Ferlin et. al. [29] the most deletions are AZFc-b2/b4 subtype and they were associated with variable spermatogenetic phenotype, with present sperm in 72% of the cases. Complete deletions in AZFa and AZFb (P5/Proximal P1) are associated only with the Sertoli cells syndrome and changes in maturation of the spermatocyte, while partial deletions in these regions are associated with milder phenotypes and the frequent presence of sperm. Men with deletions AZFc-b2/b4 produce
a higher percentage of spermatozoa with nulisso-
mia of the sex chromosomes and dissomy of the
XY [29].

Carrara et. al. [34] highlight the following chro-
mosomal mosaicism for patient # 1-9, 47, XY,
+i(22p) [10]/46, XY [90]. In this sample [34], three
patients had Y-chromosome microdeletion. Mo-
zdarani and Ghoraeian [7] simultaneously detected
the DAZ gene (Deleted in azoospermia) in centro-
meres of X and Y chromosomes, and aneuploidies.
About DAZ, the PCR multiplex revealed the linked
presence of the DAZ to AZFc and the presence
of genes of basic protein Y-2 (BPY2) in one study
[39]. In the study by Gatta et. al. [12] four patients
showed no expression of DAZ in the testis despi-
te the absence of AZFc deletion in the peripheral
blood.

Kan, Ganesan and Kumar [23] highlight the
presence of Yq deletion in cases of azoospermia
with a significant mean difference of β-HCH (hexa-
chlorocyclohexane) and total HCH in relation to
reduced semen quality, suggesting corroboration
with mutagenic activity of HCH. Recurrent double
crossovers have occurred between the HERVs (hu-
man endogenous retroviral sequences), in Blanco
et al [38] resulting in the loss of a 1.5 kb inser-
tion from one HERV, an event underlying the first
ever Y chromosomal polymorphism described,
the 12f2 deletion. This event produces a substan-
tially longer segment of absolute homology and
as such may result in increased predisposition to
further intrachromosomal recombination. Intra-
chromosomal crosstalk between these two HERV
sequences can thus result in either homogenizing
sequence conversion or a microdeletion causing
male infertility. Finally, the AZFc microdeletions
may be associated with characteristics ranging
from normal fertility [7], mild oligozoospermia,
infertility, characterized by severe oligozoosper-
mia or azoospermia.

Final Considerations

Despite major advances in molecular techniques
and cellular biology, infertility is a worldwide pu-
Blic health problem. Its etiopathogenesis is not well
understood, however, it’s known the importance of
the role of microdeletion of subregions of the Y-
chromosome in the casuistry. The literature indica-
tes that deletion of AZF, especially AZFc [12, 19, 32],
is related to azoospermia [1, 5, 10, 18, 21, 26, 31,
35], oligozoospermia [10, 18, 21, 31, 36], infertility
[4, 24] or even normal fertility [7]. The absence of
other loci is also underlined by the evidence: AZFa,
AZFb, AZFd [10, 20, 21, 23, 25, 29] and although
the prevalence rates are not equidistant.

Surveys also show changes in the male hormone
physiology varying the levels of testosterone/LH/FSH
[17, 25] as well as modifying the gonadal morpho-
logy in individuals affected by the microdeletion of
Y-chromosome [24, 35].

Therefore, more research is needed focusing on
possible deletions that the Y-chromosome may su-
ffer, giving emphasis on its clinical outcomes and
 correlations with infertility, so that you can draw
effective affirmative action policies, and methods
of early detection of male infertility.
